## Light scattering titration of $\mathbf{P M 2} \mathbf{V P}_{41} \boldsymbol{b}$ - PEO $_{204}$ with $\mathbf{P A A}_{162}$

Lindhoud et al. and Brzozowska et al. have reported that C 3 Ms formed from $\mathrm{PAA}_{139}$ and PM2 $\mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ are most stable around pH 7 and $f_{+}=0.5 .{ }^{\mathrm{S} 1, \mathrm{~S} 2} f_{+}$is here defined as follows:

$$
\begin{equation*}
f_{+}=\frac{\left[n_{+}\right]}{\left[n_{+}\right]+\left[n_{-}\right]} \tag{1}
\end{equation*}
$$

where $\left[n_{+}\right]$and $\left[n_{-}\right]$are the number concentrations of positively and negatively chargeable monomers, respectively. To verify that a $1: 1$ ratio of PM 2 VP to PAA monomers gives most stable C 3 Ms at pH 7.1, we have performed a dynamic light scattering titration of $\mathrm{PM} 2 \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ with $\mathrm{PAA}_{162}$. The light scattering intensity, normalized by the total polymer concentration ( $I / C_{\mathrm{p}}$ ), and hydrodynamic radius of the C 3 Ms are plotted in Figure S 1 as a function of $f_{+}$. We indeed find a maximum in both $I / C_{\mathrm{p}}$ and $R_{\mathrm{h}}$ around $f_{+}=0.5$. Since the position of this maximum is likely to be independent of the PAA and PM2VP length, we have used $f_{+}=0.5$ for all combinations of PAA ${ }_{m}$ and $\mathrm{PM}_{2} \mathrm{VP}_{n}-b-\mathrm{PEO}_{o}$.

Figure S1: Light scattering intensity, normalized by the total polymer concentration, and hydrodynamic radius versus $f_{+}$for a titration of $0.50 \mathrm{~g} / \mathrm{L}$ PM $2 \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ with $1.0 \mathrm{~g} / \mathrm{L} \mathrm{PAA} 162$, both at $c_{\mathrm{s}}=10 \mathrm{mM}$ and $\mathrm{pH} 7.1 \pm 0.2 . C_{\mathrm{p}}$ ranged between $0.50 \mathrm{~g} / \mathrm{L}\left(f_{+}=1.0\right)$ and $0.68 \mathrm{~g} / \mathrm{L}\left(f_{+}=0.12\right)$.

## Determination of $c_{s, c r}$ from a light scattering salt titration curve

Figure S 2 shows how we estimate the critical salt concentration from a light scattering salt titration curve (see main text). We choose the intensity curve of $\mathrm{PAA}_{20} / \mathrm{PM}_{2} \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ as an example, because it has a clear breakpoint. In this example, the 'baseline intensity' $I_{\mathrm{b}}=2.4 \mathrm{kHz} / \mathrm{mM}$. The critical salt concentration, i.e., the highest salt concentration for which the average $I / c_{\mathrm{AA}}$ of three subsequent points is larger than $2 I_{\mathrm{b}}$, is 0.27 M . If we used a threshold of $3 I_{\mathrm{b}}$, this would give $c_{\mathrm{s}, \mathrm{cr}}$ $=0.26 \mathrm{M}$, hence we estimate the error as $0.27-0.26=0.01 \mathrm{M}$.

Figure S2: Light scattering intensity, normalized by the acrylic acid monomer concentration, versus salt concentration for a mixture of $\mathrm{PAA}_{20}$ and $\mathrm{PM} 2 \mathrm{VP}_{41}-b-\mathrm{PEO}_{204} . c_{\mathrm{AA}}$ ranged from 1.1 mM at $c_{\mathrm{s}}=0.01 \mathrm{M}$ to 0.57 mM at $c_{\mathrm{s}}=0.48 \mathrm{M}$. The numbers without units are in $\mathrm{kHz} / \mathrm{mM}$. The average $I / c_{\mathrm{AA}}$ of the three blue-circled points $=6.2 \mathrm{kHz} / \mathrm{mM}>2 I_{\mathrm{b}}$, hence $c_{\mathrm{s}, \mathrm{cr}}=0.27 \mathrm{M}$. The average $I / c_{\mathrm{AA}}$ of the three green-circled points $=11.4 \mathrm{kHz} / \mathrm{mM}>3 I_{\mathrm{b}}$, hence the error is $0.27-0.26 \mathrm{M}=$ 0.01 M .

## Reversibility of response of $\mathbf{P A A}_{1728} / \mathbf{P M} 2 \mathbf{V P}_{41}-\boldsymbol{b}-\mathrm{PEO}_{204}$ to salt

Figure S3 shows the combined results of a light scattering salt and dilution titration for a mixture of $\mathrm{PAA}_{1728}$ and $\mathrm{PM} 2 \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$. The normalized scattering intensity (a), mean apparent hydrodynamic radius (b), and critical salt concentration $\left(c_{\mathrm{s}, \mathrm{cr}}=0.45 \mathrm{M}\right)$ are approximately the same in both titrations, from which we conclude that the C3Ms respond reversibly to the salt concentration. These results provide evidence that our C 3 Ms are in or close to thermodynamic equilibrium.

Figure S3: Salt and dilution titration curves for a mixture of $\mathrm{PAA}_{1728}$ and $\mathrm{PM}_{2} \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$. (a) Light scattering intensity, normalized by the acrylic acid monomer concentration, and (b) mean apparent hydrodynamic radius, as a function of salt concentration. The arrows indicate the direction of the titration. The symbols are averages of four independent runs. In (b), only data points up to the critical salt concentration are shown, with the error bars representing the standard deviations. In the salt titration, $c_{\mathrm{AA}}$ ranged from 4.4 mM at $c_{\mathrm{s}}=0.01 \mathrm{M}$ to 1.4 mM at $c_{\mathrm{s}}=0.70 \mathrm{M}$. In the dilution titration, $c_{\mathrm{AA}}$ ranged from 4.4 mM at $c_{\mathrm{s}}=0.70 \mathrm{M}$ to 1.1 mM at $c_{\mathrm{s}}=0.17 \mathrm{M}$.

## Determination of critical PAA lengths from Figure 2a (main text)

To determine the critical PAA lengths of the three diblock copolymers, we have fitted two types of trendlines to the data in Figure 2a of the main text: horizontal trendlines to the hydrodynamic radii that are independent of $N_{\text {PAA }}$, and power-law trendlines to the radii that increase with increasing $N_{\text {PAA }}$. For PM2 $\mathrm{VP}_{128}-b-\mathrm{PEO}_{477}$ and $\mathrm{PM} 2 \mathrm{VP}_{249}-b-\mathrm{PEO}_{134}$, we have determined the critical PAA length from the intersection between these trendlines, which gives $N_{\text {cr }}=1.4 \times 10^{3}$ and $3.5 \times 10^{3}$, respectively. For $\mathrm{PM}_{2} \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$, however, the choice which points to include in the powerlaw trendline is ambiguous. We have therefore fitted two power-law trendlines: one to the four points with $N_{\text {PAA }} \geq 1728$ and one to the three points with $N_{\text {PAA }} \geq 4200$. The intersection points of these trendlines with the corresponding horizontal trendline are at $N_{\text {PAA }}=1.5 \times 10^{3}$ and $2.3 \times 10^{3}$. In Figure 2a of the main text, we show an 'average' of these two power-law trendlines, which passes through their common point and intersects the horizontal trendline at $\frac{2.3-1.5}{2} \times 10^{3}=1.9 \times$ $10^{3}=N_{\mathrm{cr}}$. We have estimated the error in $N_{\mathrm{cr}}$ as $(2.3-1.9) \times 10^{3}=0.4 \times 10^{3}$.

## Effect of salt on the CMCs of PAA $_{13} / \mathbf{P M}_{2} \mathbf{V P}_{41}-\boldsymbol{b}-\mathbf{P E O}_{204}$ and

## $\mathbf{P A A}_{139} / \mathbf{P M} 2 \mathbf{V P}_{41} \boldsymbol{-} \boldsymbol{b}$ PEO $_{204}$

Figure S4 shows the effect of salt on the critical micelle concentrations of $\mathrm{PAA}_{13} / \mathrm{PM}_{2} \mathrm{VP}_{41}-b-$ $\mathrm{PEO}_{204}$ and $\mathrm{PAA}_{139} / \mathrm{PM}_{2} \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$. We have determined these CMC values by performing light scattering salt titrations for different initial polymer concentrations, and using the fact that $c_{\text {AA }}$ at $c_{\mathrm{s}, \mathrm{cr}}$ equals the CMC at that salt concentration. Following the example of Wang et al., ${ }^{\mathrm{S} 3}$ we have fitted these data by a single-exponential dependence on the square root of the salt concentration. Clearly, the dependence of $c_{\mathrm{s}, \text { cr }}$ on $c_{\mathrm{AA}}$ becomes negligible for high polymer concentrations. We also notice that this dependence seems to decrease with increasing PAA length. Since $N_{\text {PAA }}=13$ is the smallest PAA length in our experiments, we believe that we can reliably neglect concentration effects for all the C3Ms we have studied.

Figure S4: Critical micelle concentrations of C3Ms of $\mathrm{PM}_{2} \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ and $\mathrm{PAA}_{13}$ or $\mathrm{PAA}_{139}$ as a function of salt concentration. Symbols are experimentally determined CMC values. Solid lines are best-fit exponential dependences of the CMC on the square root of the salt concentration. Error bars represent the estimated error in the critical salt concentrations, as described in the Experimental details of the main text.

## Estimation of the length of the worm-like micelles from $D_{\mathrm{r}}$

To calculate the length of the worm-like micelles from their rotational diffusion coefficient $\left(D_{\mathrm{r}}\right)$, we have approximated the micelles as rigid spherocylinders, i.e., cylinders capped with hemispheres at both ends. The rotational diffusion coefficient of such structures can be expressed as a function of their average length $(L)$ and diameter $(d)$ according to: ${ }^{\text {S4 }}$

$$
\begin{equation*}
D_{\mathrm{r}}=\frac{3 k_{\mathrm{B}} T}{\pi \eta L^{3}}\left(\ln (L / d)+X_{\mathrm{r}}(L / d)\right) \tag{2}
\end{equation*}
$$

where $\eta$ is the solvent viscosity and $X_{\mathrm{r}}(L / d)$ is an empirical shape function, which takes the form for rigid spherocylinders:

$$
\begin{equation*}
X_{\mathrm{r}}(L / d)=-0.372093-\frac{0.95622}{\sqrt[4]{L / d}}+\frac{1.24792}{\sqrt{L / d}}+\frac{1.23085}{L / d}-\frac{1.99498}{(L / d)^{2}}+\frac{1.84201}{(L / d)^{3}}-\frac{0.664147}{(L / d)^{4}} \tag{3}
\end{equation*}
$$

## Fitting of scattering curves

The scattering curves in Figure 7 of the main text were fitted to form factor models included in the SASfit software package. ${ }^{55}$ These models are described in detail in the SASfit manual. ${ }^{\text {S6 }}$ The combined SLS and SAXS data of $\mathrm{PAA}_{13} / \mathrm{PM}_{2} \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ at $c_{\mathrm{s}}=10 \mathrm{mM}$ and those of $\mathrm{PAA}_{139} / \mathrm{PM}_{2} \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ at $c_{\mathrm{s}}=280 \mathrm{mM}$ were fitted to a form factor of a polydisperse coreshell sphere ('ExpShell'). This form factor consists of two contributions: (1) a monodisperse spherical core with radius $R_{\mathrm{c}}$ and uniform scattering length density $\eta_{\mathrm{c}}$, and (2) a polydisperse (Gaussian distribution) spherical shell with thickness $\Delta R$ and a scattering length density $\eta_{\exp }$ that decreases exponentially between $R_{\mathrm{c}}$ and $R_{\mathrm{c}}+\Delta R$. The best-fit parameters are shown in Table S 1 . The SAXS data of $\mathrm{PAA}_{13} / \mathrm{PM}_{2} \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ at $c_{\mathrm{s}}=180 \mathrm{mM}$ were fitted to a form factor of a polydisperse (Gaussian distribution) flexible cylinder ('WormLikeChainEXV'). The best fit was obtained for a cross-sectional radius $(R)$ of $1.5 \pm 0.4 \mathrm{~nm}$, a Kuhn length ( $l=2 l_{\mathrm{p}}$ ) of 44 nm , a contour length $(L)$ of 280 nm , and a forward scattering $\left(S_{0}\right)$ of $0.24 \times 10^{10} \mathrm{~cm}^{-2}$.

Table S1: Fitting parameters for the combined SLS and SAXS curves of (a) $\mathrm{PAA}_{13} / \mathrm{PM}_{2} \mathrm{VP}_{41}-b$ $\mathrm{PEO}_{204}$ at $c_{\mathrm{s}}=10 \mathrm{mM}$ and (b) $\mathrm{PAA}_{139} / \mathrm{PM}_{2} \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ at $c_{\mathrm{s}}=280 \mathrm{mM}$, shown in Figure 7 of the main text. A description of the parameters and the form factor model ('ExpShell') is given in the SASfit manual.

| Sample | $R_{\mathrm{c}}$ <br> $(\mathrm{nm})$ | $\Delta R$ <br> $(\mathrm{~nm})$ | $\alpha$ <br> $(-)$ | $\phi_{\text {in }}$ <br> $(-)$ | $\phi_{\text {out }}$ <br> $(-)$ | $\eta_{\mathrm{c}}$ <br> $\left(\times 10^{10} \mathrm{~cm}^{-2}\right)$ | $\eta_{\text {sh }}$ <br> $\left(\times 10^{10} \mathrm{~cm}^{-2}\right)$ | $\eta_{\text {sol }}$ <br> $\left(\times 10^{10} \mathrm{~cm}^{-2}\right)$ |

## SLS data for critical scattering analysis

Figure S 5 shows the normalized Rayleigh ratio $\left(R(q) / K c_{\mathrm{AA}}\right)$ as a function of $q^{2}$ for mixtures of $\mathrm{PAA}_{13}$ and $\mathrm{PM} 2 \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$ at five different salt concentrations. To estimate $R(0) / K c_{\mathrm{AA}}$ at each salt concentration, the data points in the range $0.17<q^{2}<0.46 \times 10^{10} \mathrm{~cm}^{-2}$ were linearly extrapolated to $q^{2}=0$. In Figure 8 of the main text, $R(0) / K c_{\mathrm{AA}}$ is plotted as a function of the separation from the critical salt concentration $\left(c_{\mathrm{s}, \mathrm{cr}}-c_{\mathrm{s}}\right)$.

Figure S5: Analysis of critical scattering from C3Ms of $\mathrm{PAA}_{13}$ and $\mathrm{PM} 2 \mathrm{VP}_{41}-b-\mathrm{PEO}_{204}$. The normalized Rayleigh ratio is plotted as a function of $q^{2}$ for five different salt concentrations, as indicated by the labels. The polymer concentration ( $c_{\mathrm{AA}}$ ) ranged from 4.4 mM at $c_{\mathrm{s}}=10 \mathrm{mM}$ to 3.6 mM at $c_{\mathrm{s}}=200 \mathrm{mM}$.
